Abstract

The recent development of automatised methods that can score various behaviours on a large number of animals provides biologists with an unprecedented set of tools to decipher these complex phenotypes. Analysing such data comes with several challenges that are largely shared across acquisition platform and paradigms. In the article herein, we present rethomics, a set of R packages that unifies analysis of behavioural dataset in an efficient and flexible manner. rethomics offers a computational solution to store, manipulate and visualise large amounts of behavioural data. We propose it as a tool to fill the gap between behavioural biology and data sciences, thus connecting computational and behavioural scientists. Our software comes with a extensive documentation as well as a set of both practical and theoretical tutorials (available https://rethomics.github.io.

Introduction

The behaviour of an animal is a complex phenotypical manifestation of the interaction between its nervous system, internal state and environment. In the last few decades, our ability to record vast quantities of various phenotypical data has tremendously increased [1]. The scoring of behaviours is certainly not an exception to this trend [2]. Indeed, many platforms have been developed in order to allow biologists to continuously record behaviours such as activity [3], position [4] and feeding [5,6] of single or multiple [7,8] animals over long durations (days or weeks).

The availability of large amounts of data paves the way for in-depth quantitative analyses which, in turn, leads to the characterisation of new principles and ultimately a better understanding of their underlying biology [9,10]. The multiplicity of model organisms, hypotheses and paradigms makes the existence of a diverse set of recording tools important. However, when it comes to the subsequent processing of the results,

PLOS 1/12

there is no unified, programmatic, framework that could be used as a palette of building blocks in a pipeline.

Scripting interfaces are the standard in data sciences and statistics since they help delivering reproducible results [11,12]. In addition such tools can be used on remote resources such as computer clusters, which makes them more scalable to the context of 'big data' [13]. For example, the field of bioinformatics benefits from sharing standard files formats, modular command line tools [14] and software packages [15] that can be assembled to build pipelines [16]. Since many aspect of behaviour analysis are are becoming increasingly linked to data sciences, the development of common tools and data structures would be an interesting resource to the community. Behavioural experiments result in sets of long time series (sometimes multivariate and irregular), the data, but also involve a formal description of the treatment applied to each individual. Such implicit structure is consistent between acquisition platforms and experimental paradigms, which broaden the scope for developing of utilities an shared principles.

In the article herein, we describe the **rethomics** platform, a collection of packages offering a solution to import, store, manipulate and visualise large amounts of behavioural data. We also present two examples of application: the analysis of circadian rhythm in fruit flies.

Design and Implementation

rethomics is implemented in R [17], since it is widely taught and adopted by computational biologists, as a collection of packages related to one another (Fig 1).

This architecture paradigm follows the model of modern frameworks such as the tidyverse [18], which results in increased testability and maintainability. In it, the different tasks of the analysis workflow (i.e. data import, manipulation and visualisation) are explicitly handled by different packages. At the core of rethomics, the behave package offers a very flexible and efficient solution to store large amounts data (e.g. position and activity) as well as metadata (e.g. treatment and genotype) in a single data.table-derived object [19]. Any input package will import experimental data as a behave table which can, in turn, be analysed and visualised regardless of the original input platform. Results and plots integrate seamlessly into the R ecosystem, hence providing users with state-of-the-art visualisation and statistical tools.

Fig 1. The rethomics workflow. Diagram representing the interplay between, from left to right, the raw data, the rethomics packages (in blue) and the rest of the R ecosystem.

Internal data structure

We created behavr (Fig 2A), a new data structure, based on the widely adopted data.table object, in order to address two challenges that are inherent to handling ethomics results.

Firstly, there could be very long (typically $k_i > 10^8, \forall i \in [1, n]$), multivariate (often, q > 10), time series for each individual. For instance, each series could represent variables that encode coordinates, orientation, dimensions, activity, colour intensity and so on, sampled several times per second, over multiple days. Therefore, the data structure must be computationally efficient – both in term of memory footprint and processing speed.

Secondly, a large number of individuals are often studied (typically n > 100). Each individual (i) is associated with metadata: a set of p "metavariables" that describe

PLOS 2/12

experimental conditions. For instance, metadata stores information regarding the date and location of the experiment, treatment, genotype, sex, post hoc observations and other arbitrary metavariables. It is interesting to record multiple metavariables since they can later be used as covariates. Therefore, typically p > 10.

behavr tables link metadata and data within the same object, extending the syntax of data.table to manipulate, join and access metadata (Fig 2B). This approach guarantees that any data point can be mapped correctly to its parent metadata. It also allows implicit update of metadata when data is altered. For instance, when is data filtered, only the remaining individuals should be in the new metadata. It is also important that metadata and data can interoperate. For instance, when one wants to update a variable according to the value of a metavariable (say, alter the variable x only for animals with the metavariable x only x only

Fig 2. behave table. A: Illustration of a behave object, the core data structure in rethomics. The metadata holds a single row for each of the n individuals. Its columns, the p metavariables, are one of two kinds: either required – and defined by the acquisition platform (i.e. used to fetch the data) – or user-defined (i.e. arbitrary). In the data, each row is a "read" (i.e. information about one individual at one time-point). It is formed of q variables and is expected to have a very large number of reads, k, for each individual i. Data and metadata are implicitly joined on the id field. Note that the names used in this for variables and metavariable in this example are only plausible cases which will likely differ in practice. B: Non exhaustive list of uses of a behave table (referred as dt). In addition to operations on data, which are inherited from data.table, we provide utilities designed specifically to act on both metadata and data. Commented examples are prefixed by >.

Data import

Data import packages translate results from a recording platform (e.g. text files and databases) into a single behavr object. Currently, we provide a package to read single or multi-beam Drosophila Activity Monitor System (Trikinetics Inc.) data and another one for Ethoscope data [20]. Although the structure of the raw results is very different, conceptually, loading data is very similar. In all cases, the user is asked to generate a metadata table (one row per individual). In it, there will be both mandatory and optional columns. The mandatory ones are the necessary and sufficient information to fetch data (e.g. machine id, region of interest and date). The optional columns are user-defined arbitrary fields that translate experimental conditions (e.g. treatment, genotype and sex).

In this respect, the metadata file is a standardised and comprehensive data frame describing an experiment. It explicitly lists all treatments and individuals, which facilitates interspersion of conditions (indeed, without it, users are tempted to simplify their experimental design by, for instance, confounding device/location and treatment). Furthermore, it streamlines the inclusion and analysis of further replicates in the same workflow. Indeed, additional replicates can simply be added as new rows – and the ID of the replicate later used, if needed, as a covariate.

Visualisation

Long time series often need to be preprocessed before visualisation. Typically, users are interested in understanding individual or population trends over time. To integrate visualisation in rethomics, we implemented ggetho, a package that offers new tools

PLOS 3/12

that extent the widely adopted ggplot2 [21]. It provides preprocessing utilities as well as new layers and scales. Our tools make full use of the internal behavr structure to deliver efficient representations of temporal trends. It particularly applies to the visualisation of long experiments, with the ability to, for instance, display "double-plotted actograms", periodograms, annotate light and dark phases and wrap time over a given period. Importantly, ggetho is fully compatible with ggplot2.

Circadian and sleep analysis

The packages **zeitgebr** and **sleepr** provide tools to analyse circadian behaviours and sleep, respectively. Together, they offer a suite of methods to compute autocorrelogram, χ^2 [22] and Lomb-Scargle [23] periodograms and find their peaks, score sleep from inactivity (*i.e.* using the "five-minute rule"), and characterise the architecture of sleep bouts (*e.g.* number, length and latency).

Results

In order to illustrate the workflow of rethomics, we provide a straightforward and simplified example which could be readily modified for more intricate cases.

The study of circadian rhythm, employing fruit flies as an animal model, is a well established research field recently awarded with the Nobel Prize in Physiology or Medicine. Importantly, DAM2 (the second, and most popular, version of the Drosophila Activity Monitors System) is the most widely adopted behaviour recording platform in this research field. We gathered a subset of the data from a recent publication [24], which was graciously made publicly available by the authors [25]. Wild type flies are highly rhythmic in Light-Dark (LD) cycles and become arrhythmic in constant light (LL). In their study, the authors gain understanding of the function of the molecular clock by showing that overexpression of the gene NKCC makes the flies rhythmic in both LD and LL, and that the endogenous period in LL is longer than 24 hours.

We took two genotypes employed in the study, one control group (NKCC^{ox}/+) and one where NKCC^{ox} is overexpressed in all clock neurons (TIM/NKCC^{ox}). In particular, we re-analysed two repetitions of the same experiment in which a total of 58 animals were recorded for three to four days in LD and then subjected to constant light for six days. The metadata.csv file, which describes exhaustively all individuals, as well as all the associated result files can be downloaded at https://zenodo.org/record/1172980. As a prerequisite, we downloaded the data, extracted the zip archive in our working directory. We start the analysis by loading the necessary rethomics packages (see availability section for installation instructions):

```
library(damr) # input DAM data
library(zeitgebr) # periodogram computation
library(sleepr) # sleep analysis
library(ggetho) # behaviour visualisation
```

Then, the metadata file is read and linked to the .txt result files.

```
metadata <- link_dam_metadata("metadata.csv", ".")  # linking

## Error in link_dam_metadata("metadata.csv", "."): could not find
function "link_dam_metadata"

# print(metadata)  # check metadata
dt <- load_dam(metadata)  # loading</pre>
```

PLOS 4/12

```
## Error in load_dam(metadata): could not find function "load_dam"
summary(dt)  # quick summary
## Error in object[[i]]: object of type 'closure' is not subsettable
```

Preprocessing

The two replicates do not have the same baseline time and we would like to express the time relative to the important event: the transition from LD to LL. Therefore, we subtract the baseline_days metavariable from the t variable. This gives us an opportunity to illustrate the use xmv(), which expands metavariables as variables. In addition, we use the data.table syntax to create, in place, a moving variable. It is TRUE when and only when activity is greater than zero:

```
# baseline subtraction -- note the use of xmv
dt[,t := t - days(xmv(baseline_days))]
dt[, moving := activity > 0]
```

```
summary(dt)

## behavr table with:

## 58 individuals

## 8 metavariables

## 3 variables

## 1.58722e+05 measurements

## 1 key (id)
```

To simplify visualisation, we create our own label metavariable, as the combination of a number and genotype. In the restricted context of this analysis, label acts as a unique identifier. Importantly, we keep id, which is more rigorous and universal.

```
dt[, label := interaction(1:.N, genotype), meta = T]
print(dt)
```

Curation

It is important to visualise an overview of how each individual behaved and, if necessary, alter the data accordingly. For this, we generate a tile plot (Fig 3A).

Fig 3. Experiment quality control. Tile plot showing the fraction of time spent moving as a colour intensity. Each individual is represented by a row and time, on the x-axis, is binned in 30 minutes. A: Uncurated raw data. B: Data after the curation step. Time was trimmed and data from dead animals removed. Red '+' symbols show animals that were removed from the subsequent analysis as they had less than five complete days in LL.

PLOS 5/12

The activity of dead or escaped animals is falsely scored as long series of zeros (see, for instance, individual 30 and 18 in Fig 3A). Our sleepr package offers a tool to detect and remove such artefactual data.

```
# remove data after death
dt <- sleepr::curate_dead_animals(dt, moving)</pre>
```

In addition, we can trim our data to have the same number of days across experiments and individuals.

For the purpose of this example, we also exclude animals that died prematurely, and keep only individuals that have *at least five days in LL*. An overview of the curate data can be visualised in Fig 3B.

```
# for each id, we check for validity
valid_dt <- dt[, .(valid = max(t) > days(5)), by = id]
# a vector of all valid ids
valid_ids <- valid_dt[valid == T, id]
# filter dt with the valid ids
dt <- dt[id %in% valid_ids]
summary(dt)

## behave table with:
## 52 individuals
## 9 metavariables
## 3 variables
## 1.19546e+05 measurements
## 1 key (id)</pre>
```

Note that as a result, we now have 52 "valid" individuals.

PLOS 6/12

Double-plotted actograms

"Double-plotted actograms" are a common visualisation of periodicity and rhythmicity in circadian experiments. In S1 FigA, we show the double-plotted actograms of each animal. A representative sample of four individuals for each genotype is shown in Fig 4A.

Periodograms

Ultimately, in order to quantify periodicity and rhythmicity, we compute periodograms. Several methods are implemented in zeitbebr: χ^2 , Lomb-Scargle, autocorrelation and Fourier. In this example, we generate χ^2 periodograms and lay them out in a grid. Periodograms for the subset of eight animals used in Fig 4A is shown in Fig 4B. See S1 FigB for the visualisation of all individuals.

```
# only the LL data
dt_ll \leftarrow dt[t > days(1)]
# compute chi sqr periodogram
per_dt <- periodogram(moving,</pre>
                         dt_ll,
                         resample_rate = 1 / mins(10),
                         FUN=chi_sq_periodogram)
per_dt <- find_peaks(per_dt)</pre>
# we also show a subset of this figure in supplementary materials
figS1B <- ggperio(per_dt, aes(y = power, peak = peak)) +
                   # periododogram drawn as a line
                   geom_line() +
                   # the significance line in red
                   geom_line(aes(y = signif_threshold), colour = "red") +
                   # point and text at the peak
                   geom_peak() +
                   # divide plot by individual
                   facet_wrap( ~ label, ncol = 4)
```

Fig 4. Visualisation of the periodicity in activity of eight representative animals. A: Double-plotted actograms showing activity over the experiment. Transition from LD to LL happens at day 0. B: χ^2 periodograms over the LL part of the experiment matching the animals in A. The blue cross represents the first peak (if present) above the significance threshold (red line). Titles on top of each facet refer to the label allocated to each individual. See S1 Fig for all 52 animals.

PLOS 7/12

Population statistics

As shown in the original study, double-plotted actograms and periodograms suggest that NKCC^{ox}/+ flies are mostly arhythmic in LL whilst Tim/NKCC^{ox} appear to have a consistent, long-period rhythm. To visualise this at the population scale, we can plot an average periodogram (see Fig 5A):

Fig 5. Population statistics on circadian phenotype. A: Average periodograms. The aggregated relative power of the periodogram of all animals. The solid lines and the shaded areas show population means and their 95% bootstrap confidence interval, respectively. B: Frequencies of rhythmic animals. Number of rhythmic animals (*i.e.* with a significant peak) in each genotypes. Dark and clear fillings indicate rhythmic and arhythmic animals, respectively. C: Peak periodicity power and average. Values of the peak period for animals with a significant peak (*i.e.* rhythmic). Individual animals are shown by dots whose size represent relative power of the peak period. The error bars are 95% bootstrap confidence interval on the population mean.

To further quantify this difference, we can show the number of rhythmic animals – *i.e.* individuals for which a peak was found – in each group (see Fig 5B). Then, we can compare the average value of the peak for the rhythmic animals (see Fig 5C). First of all, we compute a summary per individual (by=id):

summary_dt is just a regular data frame with one row per individual, containing
both metadata and our summary statistics. It can therefore be used directly by ggplot
and other tools:

PLOS 8/12

R provides one of the richest statistical toolbox available, which allows users to go deeper in the analysis of the extracted variables. One could, for instance, perform a χ^2 test on the number of rhythmic vs arbythmic flies in both genotypes. To address the same question, we fit a binomial generalised linear model:

The result shows a strong positive effect of genotype Tim/NKCC^{ox} on the probability of being rhythmic (p-value 6.27×10^{-06}):

Lastly, we can generate a table that compute arbitrary population statistics for each genotype:

PLOS 9/12

```
## genotype mean_period sd_period n_rhythmic n percent_rhythmic
## 1: NKCCOX/+ 25.22500 3.598495 4 22 18.18182
## 2: Tim/NKCCOX 26.21429 2.363568 28 30 93.33333
```

This example shows how rethomics can be used from the raw data to making publication-quality figures and statistics. We were able to comprehensively analyse the data from a circadian experiment with a few line of code. This workflow applies particularly to much larger data sets and provides a large degree of flexibility that will allow biologists to tune their analysis to their specific questions.

Availability and Future Directions

All packages in the rethomics framework are available under the terms of the GPLv3 license and listed at https://github.com/rethomics/. Extensive installation instructions as well as reproducible demos and tutorials are available at https://rethomics.github.io/. All packages are continuously integrated and unit tested on several version of R to minimise the risk of present and future issues.

Several users, in different research groups, have already adopted and are contributing to the future development framework. Several new packages in the rethomics framework are currently envisaged. They include utilities to input new behaviour tracking methods and analyse position and multi-animal interactions.
